Form for the Diagnosis of Death using Neurological Criteria (abbreviated guidance version)

This form is consistent with and should be used in conjunction with, the AoMRC (2008) A Code of Practice for the Diagnosis and Confirmation of Death and has been endorsed for use by the Faculty of Intensive Care Medicine and Intensive Care Society.

Evidence for Irreversible Brain Damage of known Aetiology

Primary Diagnosis:

Evidence for Irreversible Brain Damage of known Aetiology:

Diagnostic caution is advised in certain ‘Red Flag’ patient groups. See Page 3 for details.

Exclusion of Reversible Causes of Coma and Apnoea

September 2015
Form for the Diagnosis of Death using Neurological Criteria (abbreviated guidance version)

It remains the duty of the two doctors carrying out the testing to be satisfied with the aetiology, the exclusion of all potentially reversible causes, the clinical tests of brain-stem function and of any ancillary investigations so that each doctor may independently confirm death following irreversible cessation of brain-stem function.

Guidance Summary of the AoMRC Code of Practice
The diagnosis of death by neurological criteria should be made by at least two medical practitioners who have been registered for more than five years and are competent in the conduct and interpretation of brain-stem testing. At least one of the doctors must be a consultant. Testing should be performed completely and successfully on two occasions with both doctors present. It is recommended that one doctor perform the test while the other doctor observe; roles may be reversed for the second test.

Diagnostic caution is advised in the following 'Red Flag' patient groups.
(Based on the literature and unpublished case reports.)

1. Testing < 6 hours of the loss of the last brain-stem reflex
2. Testing < 24 hours where aetiology primarily anoxic damage
3. Hypothermia (24 hour observation period following re-warming to normothermia recommended)
4. Patients with any neuromuscular disorders
5. Steroids given in space occupying lesions such as abscesses
6. Prolonged fentanyl infusions
7. Aetiology primarily located to the brain-stem or posterior fossa

Evidence for Irreversible Brain Damage of Known Aetiology
- There should be no doubt that the patient's condition is due to irreversible brain damage of known aetiology. Occasionally it may take a period of continued clinical observation and investigation to be confident of the irreversible nature of the prognosis. The timing of the first test and the timing between the two tests should be adequate for the reassurance of all those directly concerned. If in doubt wait and seek advice.

Children (one examining doctor should normally be a paediatrician or should have experience with children and one of the doctors should not be primarily involved in the child's care)
- Older than 2 months post term: This guideline can be used in these children.
- Between thirty seven weeks corrected gestation (post menstrual) age to 2 months of age post term: use the RCPCH Guidance available at www.rcpch.ac.uk
- Infants less than 37 weeks corrected gestation (post menstrual) age: the concept of brain-stem death is inappropriate for infants in this age group.

Drugs
- The patient should not have received any drugs that might be contributing to the unconsciousness, apnoea and loss of brainstem reflexes (narcotics, hypnotics, sedatives or tranquillisers). Where there is any doubt specific drug levels should be carried out (midazolam less than < 10mcg/L, thiopentone <5mg/L). Alternatively consider ancillary investigations.
- There should be no residual effect from any neuromuscular blocking agents (atracurium, vecuronium or suxamethonium), consider the use of peripheral nerve stimulation.
- Renal or hepatic failure may prolong metabolism / excretion of these drugs.

Temperature, Circulatory, Metabolic or Endocrine Disorders
- Prior to testing aim for: temperature > 34°C, mean arterial pressure consistently >60mmHg (or age appropriate parameters for children), maintenance of normocarbia and avoidance of hypoxia, acidaemia or alkalaeemia (PaCO2 <6.0 kPa, PaO2 >10 kPa and pH 7.35 – 7.45 / [H+] 45-35 nmol/L).
- Serum Na⁺ should be between 115-160mmol/L; Serum K⁺ should be > 2mmol/L; Serum PO₂ and Mg²⁺ should not be profoundly elevated (>3.0mmol/L) or lowered (<0.5mmol/L) from normal.
- Blood glucose should be between 3.0-20mmol/L before each brain-stem test.
- If there is any clinical reason to expect endocrine disturbances then it is obligatory to ensure appropriate hormonal assays are undertaken.
Form for the Diagnosis of Death using Neurological Criteria (abbreviated guidance version)

Brain Stem Reflexes
- Pupils should be fixed in diameter and unresponsive to light.
- There should be no corneal (blink) reflex (care should be taken to avoid damage to cornea).
- Eye movement should not occur when each ear is instilled, over one minute, with 50mls of ice cold water, head 30°. Each ear drum should be clearly visualised before the test.
- There should be no motor response within the cranial nerve or somatic distribution in response to supraorbital pressure. Reflex limb and trunk movements (spinal reflexes) may still be present.
- There should be no gag reflex following stimulation to the posterior pharynx or cough reflex following suction catheter placed down the trachea to the carina.

Apnoea Test
- End tidal carbon dioxide can be used to guide the starting of each apnoea test but should not replace the pre and post arterial PaCO₂.
- Oxygenation and cardiovascular stability should be maintained through each apnoea test.
- Confirm PaCO₂ ≥6.0 kPa and pH < 7.4 / [H⁺] >40 nmol/L. In patients with chronic CO₂ retention, or those who have received intravenous bicarbonate, confirm PaCO₂ >6.5 kPa and the pH < 7.4 / [H⁺] >40 nmoles/L.
- Either use a CPAP circuit (eg Mapleson B) or disconnect the patient from the ventilator and administer oxygen via a catheter in the trachea at a rate of >6L/minute.
- There should be no spontaneous respiration within a minimum of 5 (five) minutes following disconnection from the ventilator.
- Confirm that the PaCO₂ has increased from the starting level by more than 0.5 kPa.
- At the conclusion of the apnoea test, manual recruitment manoeuvres should be carried out before resuming mechanical ventilation and ventilation parameters normalised.

Ancillary Investigations
- Ancillary investigations are NOT required for the diagnosis and confirmation of death using neurological criteria. Any ancillary or confirmatory investigation should be considered ADDITIONAL to the fullest clinical testing and examination carried out to the best of the two doctors capabilities in the given circumstances.

Organ Donation
- National professional guidance advocates the confirmation of death by neurological criteria wherever this seems a likely diagnosis and regardless of the likelihood of organ donation.
- NICE guidance recommends that the specialist nurse for organ donation (SN-OD) should be notified at the point when the clinical team declare the intention to perform brain-stem death tests and this is supported by GMC guidance.
